

Vaultly Troubleshooting Guide

Version: 2.4.1

Last Updated: March 12, 2025

Reading Application Logs

Vaultly writes structured JSON logs to `/var/log/vaultly/app.log`. On Windows, logs are written to `C:\ProgramData\Vaultly\logs\app.log`. To tail the log in real time:

```
tail -f /var/log/vaultly/app.log
```

Each log entry includes a timestamp, log level, error code (if applicable), and a human-readable message. Filter for errors only:

```
grep '"level":"error"' /var/log/vaultly/app.log
```

Common Error Codes

VLT-1001: Database Connection Failed

Symptom: The server fails to start and the log shows VLT-1001.

Cause: Vaultly cannot reach the database specified in `VAULTLYDBURL`.

Fix: Verify that the `VAULTLYDBURL` environment variable is set correctly and that the database server is running and accessible from the Vaultly host. Check firewall rules if the database is on a separate host.

VLT-2003: Storage Quota Exceeded

Symptom: Document uploads fail with a VLT-2003 error in the API response.

Cause: The workspace has reached its storage limit.

Fix: Either delete existing files to free up space or upgrade to a higher plan via the billing portal. No automatic charges apply - uploads remain blocked until storage is freed.

VLT-4291: Authentication Token Expired

Symptom: API requests return HTTP 401 with error code VLT-4291.

Cause: The API token used in the request has been manually revoked or the session has expired after 90 days of inactivity.

Fix: Generate a new API token from Settings > API Tokens and update your application configuration with the new token value.

VLT-5500: Internal Processing Error

Symptom: Uploads succeed but documents do not appear in search results.

Cause: The background document indexing worker has crashed or is overwhelmed.

Fix: Restart the indexing worker with vaultly worker restart. If the error persists, check disk space on the host - the indexing worker requires at least 2 GB of free disk space to process large batches.

Performance Issues

Slow search results: Search latency above 2 seconds usually indicates that the search index needs rebuilding. Run vaultly index rebuild to rebuild the full-text index. This process may take several minutes for large workspaces.

High CPU usage: The embedding pipeline is CPU-intensive during bulk ingestion. Schedule large ingestion jobs during off-peak hours, or limit the concurrency by setting VAULTLYWORKERCONCURRENCY=2 in your environment.

Contacting Support

If the above steps do not resolve your issue, contact the Vaultly support team:

- * Email: support@vaultly.io
- * Response time: 8 hours for Professional, 24/7 for Enterprise
- * Portal: <https://support.vaultly.io>

When contacting support, include your Vaultly version number, the relevant error code, and the last 50 lines of `/var/log/vaultly/app.log`.
